

A photograph of a modern, multi-story glass skyscraper at dusk. The building's curved facade is illuminated from within, showing interior floors and a prominent glass-enclosed staircase. A person in a white lab coat is walking in the foreground on the right. The sky is a deep blue.

Molecular Classification of Endometrial Cancer

Emily Hinchcliff, MD MPH

Assistant Professor
Department of Obstetrics & Gynecology
Division of Gynecologic Oncology

Survive and Thrive 2022

Disclosures

None

What is cancer classification?

- Classification – grouping cancers together that act similarly
 - Allows for better decision-making regarding the best treatment options
- Many different approaches to grouping cancer
 - Pathology
 - Grade
 - Stage
 - Molecular features

Endometrial Cancer: Type I vs Type II

- Traditionally, endometrial cancer was classified into two pathologic groups using a combination of these features

Characteristic	Type I	Type II

Endometrial Cancer: Type I vs Type II

- Traditionally, endometrial cancer was classified into two pathologic groups using a combination of these features

Characteristic	Type I	Type II
Histology	Endometrioid	Non-endometrioid (serous, clear cell, carcinosarcoma, undifferentiated)

Endometrial Cancer: Type I vs Type II

- Traditionally, endometrial cancer was classified into two pathologic groups using a combination of these features

Characteristic	Type I	Type II
Histology	Endometrioid	Non-endometrioid (serous, clear cell, carcinosarcoma, undifferentiated)
Grade	Usually low (less aggressive)	Usually high (more aggressive)

Endometrial Cancer: Type I vs Type II

- Traditionally, endometrial cancer was classified into two pathologic groups using a combination of these features

Characteristic	Type I	Type II
Histology	Endometrioid	Non-endometrioid (serous, clear cell, carcinosarcoma, undifferentiated)
Grade	Usually low (less aggressive)	Usually high (more aggressive)
Stage	Often early	Often advanced

Endometrial Cancer: Type I vs Type II

- Traditionally, endometrial cancer was classified into two pathologic groups using a combination of these features

Characteristic	Type I	Type II
Histology	Endometrioid	Non-endometrioid (serous, clear cell, carcinosarcoma, undifferentiated)
Grade	Usually low (less aggressive)	Usually high (more aggressive)
Stage	Often early	Often advanced
Etiology	Unopposed estrogen	Sporadic

Endometrial Cancer: Type I vs Type II

- This classification system:
 - Grade and histopathology is not always reproducible
 - This can lead to heterogeneity in not only classification, but also research and clinical trials
 - Somewhat more limited ability to risk stratify patients

Can we do better?

An aerial photograph of Northwestern University's campus in Chicago. The image shows several large, modern buildings with glass facades and flat roofs. In the background, the blue waters of Lake Michigan are visible under a clear sky. The foreground features a large green lawn and a street with a few cars. A semi-transparent purple triangle is overlaid on the left side of the image, containing the university's logo and name.

Molecular Classification

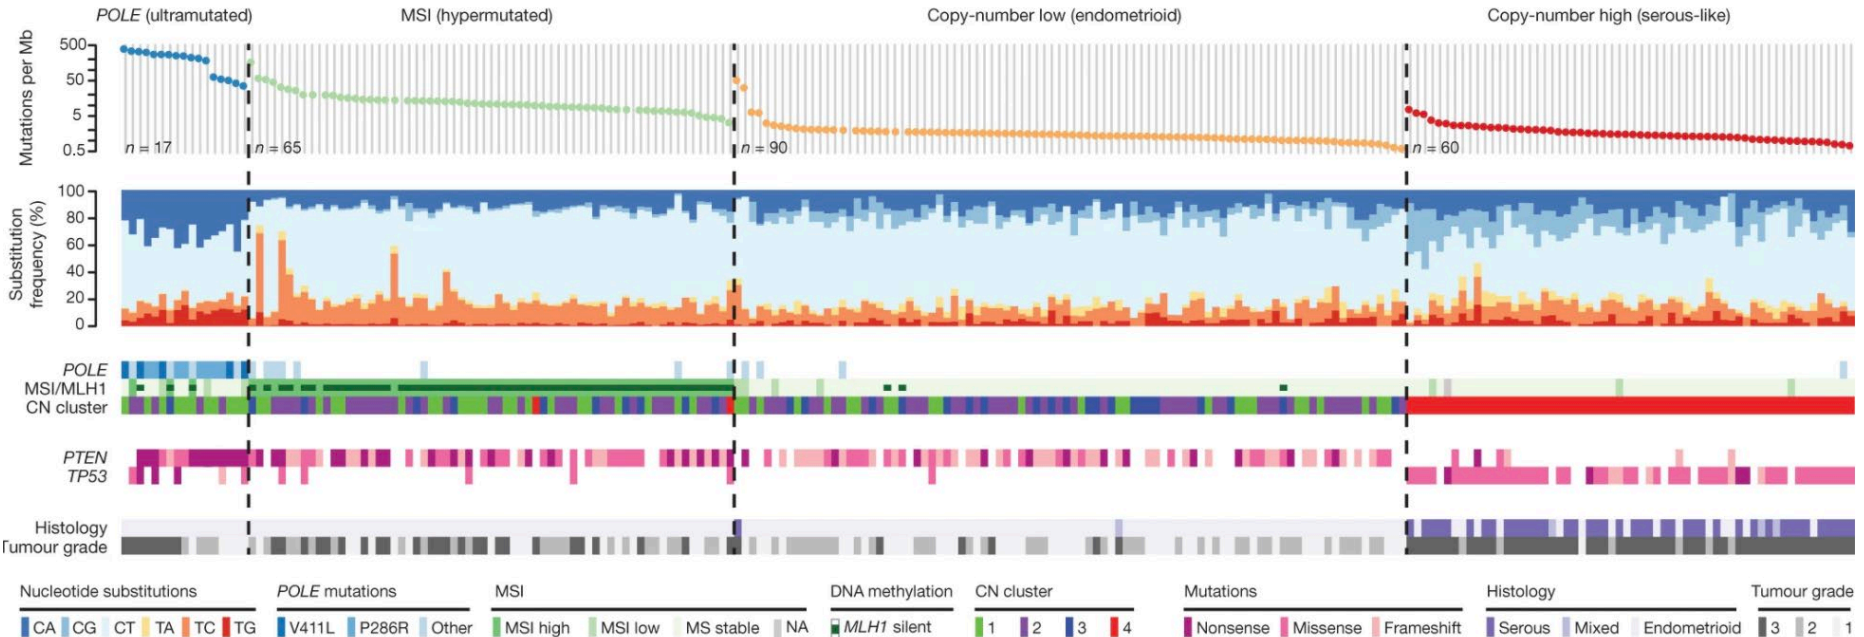

The Cancer Genome Atlas (TCGA)

- Landmark cancer genomics program
 - National Cancer Institute
 - National Human Genome Research Institute
- Molecularly characterized multiple cancer types with matched normal samples
 - 2664 cases of uterine cancer
 - Multiple histologies

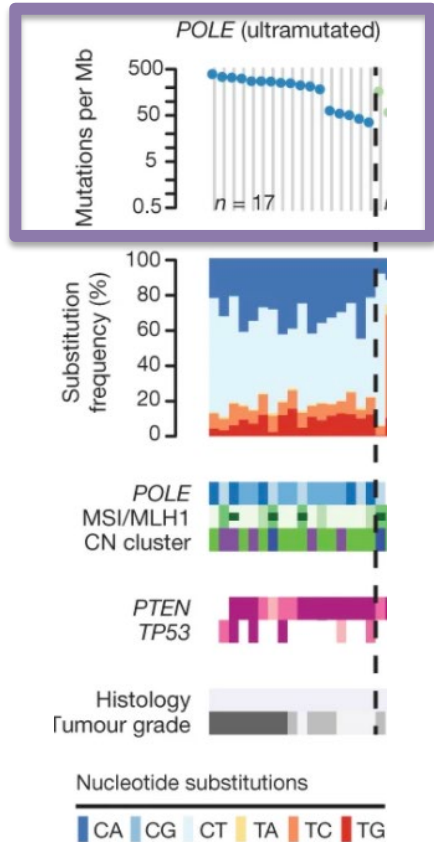

TCGA Molecular Classification

- Grouping endometrial cancer based on molecular characteristics rather than pathologic characteristics

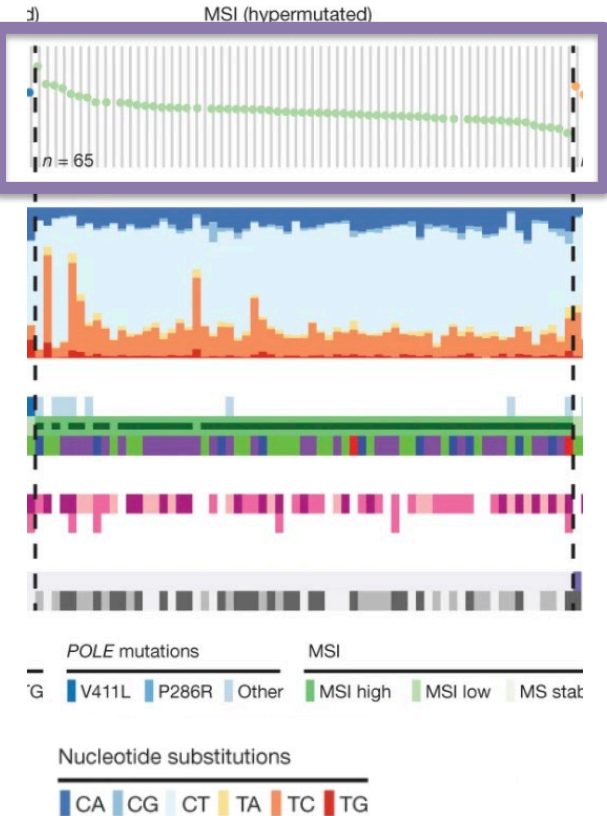

TCGA Molecular Classification: POLE

- POLE Mutation
 - 4-8% of endometrial cancers
 - Very high mutational burden
 - Excellent prognosis
 - Decreased recurrence risk

TCGA Molecular Classification: MSI or dMMR

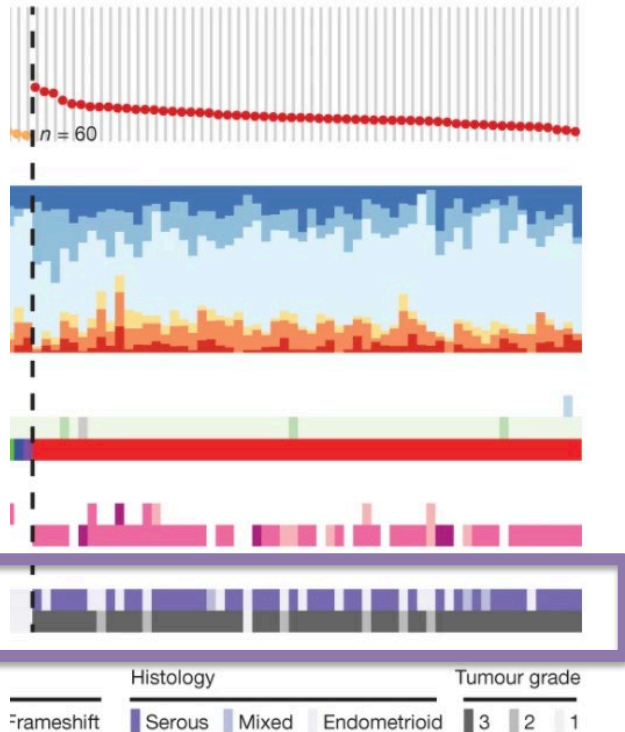

- MSI = microsatellite instability
- dMMR = deficient mismatch repair

- 20-40% of endometrial cancer
- Intermediate prognosis group
 - Predictive of response to immunotherapy

TCGA Molecular Classification: Copy number high

Copy-number high (serous-like)

- “Serous-like” (73% in this group are serous histology)
- Aggressive, poor prognosis
- P53 mutated

TCGA Molecular Classification: Copy number high

p=0.015, HR 0.50 (95%CI 0,28-0,88)

- “Serous-like” (73% in this group are serous histology)
- Aggressive, poor prognosis
- P53 mutated
 - Chemotherapy may have greater benefit for these patients than others in the adjuvant setting

TCGA Molecular Classification: Copy number low

- Also known as “no specific molecular profile” (NSMP)
- 40-50% of endometrial cancer
- Intermediate prognosis group
- Hormone receptors
- Further molecular characterization in order to stratify
 - CTNNB1
 - L1CAM

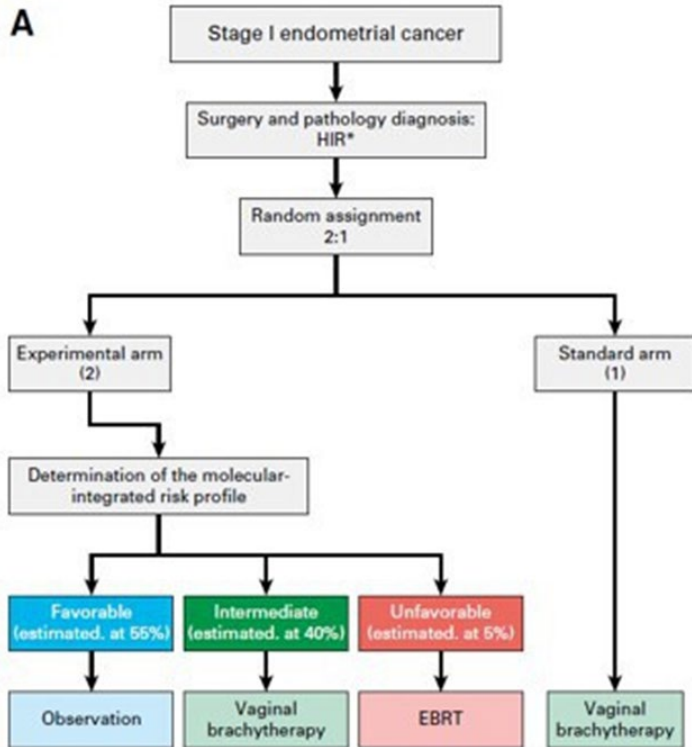

So what does that all mean, and why should you care?

Proactive Molecular Risk Classification for Endometrial cancer (ProMisE)

- Using these categories has excellent prognostic ability
- Potential to drive therapy!
 - Use of immunotherapy
 - Use of chemotherapy
- Ongoing current trial: PORTEC – 4A

Proactive Molecular Risk Classification for Endometrial cancer (ProMisE)

- Prognostic ability
- Potential to drive therapy!
- Ongoing current trial: PORTEC – 4A
 - Randomized trial of molecular profile-based versus standard recommendations for adjuvant radiotherapy for women with early stage endometrial cancer

In summary...

- We are learning more and more about how endometrial cancer acts and responds to treatment
- Molecular classification represents a new way of grouping these cancers, and gives a more nuanced view
 - This will hopefully allow us to better tailor treatment to each woman's specific tumor

Thank You!

Any questions?
